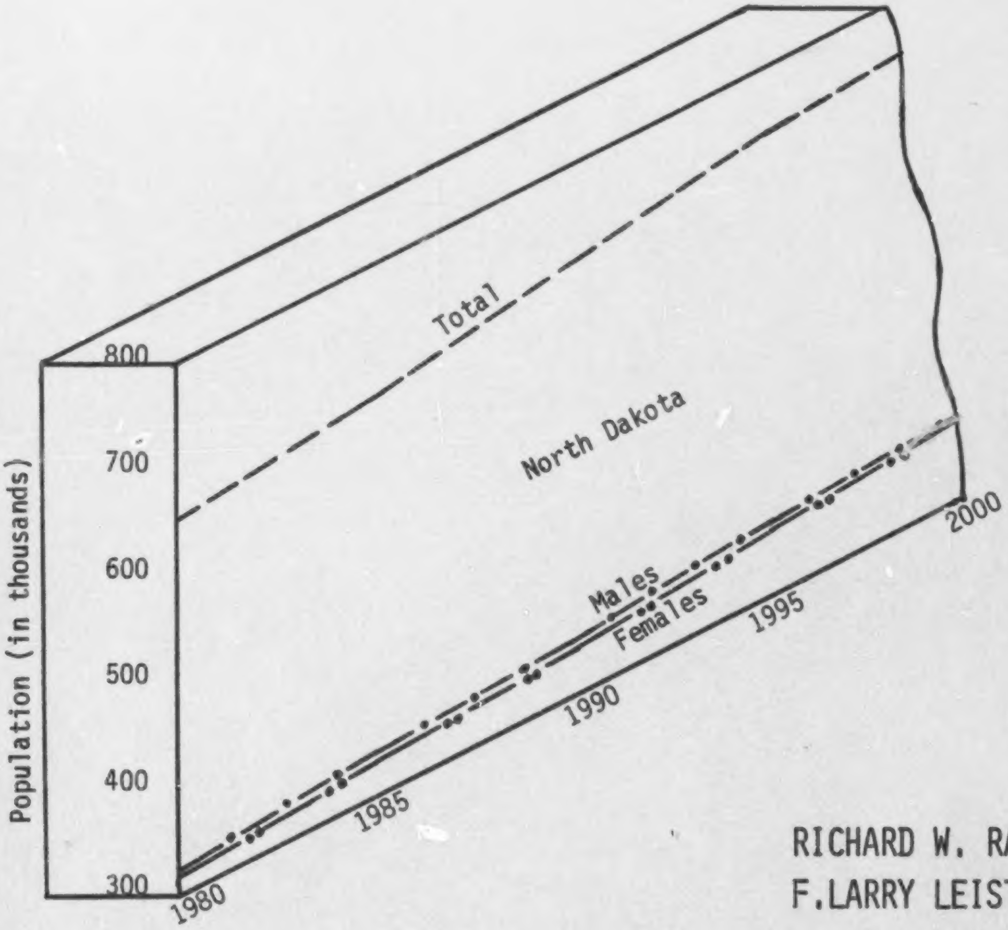
POPULATION PROJECTIONS BY AGE AND GENDER, 1980-2000, FOR NORTH DAKOTA



RICHARD W. RATHGE
F.LARRY LEISTRITZ

Department of Agricultural Economics
North Dakota Agricultural Experiment Station
North Dakota State University
Fargo, North Dakota 58105

Foreword

Population projections are useful tools for planners and policy makers. They provide a basis for assessing the future needs of a specific clientele. Moreover, foresight into increased demand for various public and private services, shifts in land use and health care needs, and numerous other alterations may mitigate detrimental consequences which could otherwise be associated with North Dakota's changing population structure.

Projections, however, are based upon historical trends and thus portray what would occur if population processes were to continue in an assumed manner. This report, utilizing 1980 census data and various current economic statistics within an economic-demographic simulation model, presents projections of North Dakota's population by gender at five year intervals from 1980 to the year 2000.

Acknowledgements

The authors wish to acknowledge members of the advisory committee who served as a review forum for these projections. Their insights, comments, and critical review provided invaluable assistance throughout the project.

Advisory Committee

Gary Garland, Director
Department of Health Planning

David Torkelson, Chief Research Analyst
North Dakota Economic Development Commission

Tom Pederson, Chief, Research and Statistics--Job Service

Richard Blair, Director

North Dakota State University

Financial assistance for these projections was received, in part, from a grant from the North Dakota State Department of Health for which the authors are grateful. Also, the authors wish to acknowledge the support of the North Dakota Agricultural Experiment Station and the North Dakota State Census Data Center.

Computer programming expertise was provided by William Ransom-Nelson, Rakesh Sharma, and Pai-Sung Yang. Their skills and dedication greatly facilitated completion of these projections, for that we are especially appreciative. Recognition is also given to Rajnish Barua and Babusankar Ranganathan for their assistance in final tabulations and layout.

Population Projections By Age and Gender, 1980-2000, For North Dakota

by

Richard W. Rathge and F. Larry Leistritz*

Introduction

This report presents projections of North Dakota's population by age and gender[1] shown in five year periods from 1980 to the year 2000. Tabulations for the state and its eight planning regions and component counties (see Figure 1) are included. This publication updates previous projections (see Murdock and Ostenson, 1976) by incorporating many of the changes which have recently occurred in North Dakota's population.

Quite dramatic shifts in various aspects of North Dakota's population have occurred during the 1970s. Seventeen of North Dakota's 53 counties expanded their population during the 1970s, nearly three times the number recorded in the 1960s. Moreover, 11 counties exhibited net in-migration from 1970-1980 while an additional 25 counties reported decreases of 10 percent or more in their net out-migration rates for the same period compared to 1960-1970. In contrast, only two counties experienced net in-migration during the decade of the 1960s. Much of the new growth is due to increased energy development, expecially in western counties of North Dakota. Concurrently, the number of births in the state dropped 21 percent compared to the previous decade. Furthermore, the proportion of elderly (65 years of age or older) in North

[1] In conducting population analyses, it is important to recognize that policy or planning decisions are often implicitly linked to the expected roles individuals may play. Sensitive to this concern, we utilize the term gender in this report since it encompasses social expectations based on sex, the biological distinction between males and females.

Dakota rose 21 percent above the 1970 level contributing to a marked increase in the median age of North Dakota residents from 26.4 in 1970 to 28.3 in 1980.

In addressing the changes in such dimensions and processes, an economic-demographic simulation model is employed for projecting the state's population. Unlike the cohort-survival method used in earlier tabulations, the simulation model accommodates dynamic populations typical in energy development areas (i.e., western North Dakota). In general, the model enhances our ability to portray what the state's population picture is likely to be in the future by incorporating various modules which provide for input from energy development indicators, nonenergy-related economic and demographic parameters, and residential allocation indices. A discussion of the assumptions upon which these projections are based and guidelines for their utilization follows a brief overview of the economic-demographic simulation model.

Economic-Demographic Simulation Model

Conceptually, the economic-demographic simulation model projects an estimate of employment demand from an economic input-output module and links it with projected labor force availability via a demographic cohort-survival module to determine employment needs (see Leistritz *et al*., 1982 for further documentation). Migration results when the resident population can not fill projected employment needs (in-migration) or in the event of an excess labor force (out-migration). Settlement patterns of new workers and their families are estimated in a separate component of the model.

Employment requirements are derived from estimates of gross business volume--an assessment of economic activity in 13 sectors (e.g., agriculture, manufacturing, construction, trade) of North Dakota's economy from 1960-1980. A correlation of employment in each economic sector, drawn from published sources (e.g., Employment Security Bureau) for the corresponding historical period, with gross business volume provides a trend by which to project employment demand.

Labor force availability is determined from a cohort-survival component which applies a set of age-specific fertility and mortality rates to a given county population for a projected period in order to determine the population at the end of that period. Concurrently, age-gender cohorts (persons of the same gender born during the same period of time) are advanced appropriately through the years--in essence aging the population--while migration rates for the elderly (65 years or older) are applied. Age-gender specific labor force participation rates are then applied to the population to determine labor force availability.

In general, the projection procedure is as follows:

1) The model begins with age-gender specific cohorts at the county level abstracted from the 1980 census of population.
2) Age-gender specific mortality rates are applied to the population, and each cohort is advanced one year.
3) Age-specific fertility rates are applied to women 15-44 years of age to determine the number of children born that year.
4) Migration rates (1970-1980) are applied to those 65 years and older to determine the number of elderly migrating in or out of each county.
5) Employment requirements reflected in gross business volume are calculated for each county.
6) Labor force availability is computed at the county level and matched to the employment needs to determine nonelderly migration (i.e., workers and associated spouses and dependents).

7) The results of the preceeding steps are accumulated to determine the population within each cohort for the first projection year. The process is repeated 20 times, in each instance utilizing the preceeding year's population as a base.

A more detailed description of the projection procedure is available in the simulation model's technical documentation (see Leistritz *et al*., 1982).

Assumptions

Various assumptions are made in the procedures outlined above of which the user of the projections should be cognizant:

Fertility

Age-specific fertility rates used in the model are derived from birth data by age of mother for North Dakota obtained from the Office of Statistical Services, North Dakota Health Department. An average of the total births in each cohort during 1979, 1980, and 1981 is used to control for year-to-year fluctuations in the number of births. Similarly, variations in female cohort sizes are controlled by calculating fertility rates for five-year age groups from 15 to 44 and disaggregating them into single-year age-specific rates. Total fertility, the sum of these age-specific rates for all cohorts, is assumed to be at the current state rate of 2.1 (population replacement level).

It is further assumed that changes in fertility patterns are likely to occur over time. In order to allow for these possible shifts, fertility rates used in the model are adjusted to project national trends, which fluctuate between 1.9 and 2.1 (see U.S. Bureau of Census, 1977), by ratioing North Dakota's 1980 age-specific fertility rates to equivalent national rates. Also, variations in fertility rates among different counties in North Dakota will most likely diminish, so a state rate is employed for all projection years.

Mortality

Statewide cohort-specific survival rates applied to 75 age-gender groups are used by the model to measure mortality. These rates are derived from a 1980 standard life table constructed from population data abstracted from the 1980 census and age-specific mortality data obtained from the Office of Statistical Services, North Dakota Health Department. Year-to-year fluctuations in the number of deaths is controlled by averaging total deaths in each cohort during 1979, 1980, and 1981. Due to the relatively low rates of mortality and limited variation between county rates, 1980 survival rates for the state as a whole are assumed to prevail within each county for all projection periods.

Migration

Migration for those in the working age group (age 14 to 64) is determined in the economic module by comparing employment requirements and available workers, as mentioned previously. Out-migration indicates available workers exceed required demand by a specified parameter; in-migration represents the opposite situation.

Concurrently, migration rates for individuals under age 14 are determined as a function of the level of migrating workers. Based on surveys, worker profiles have been developed assessing various demographic characteristics including those individuals (i.e., children, spouses) who are likely to migrate with the worker. Migration levels of children (those under age 14) therefore are contingent upon the movement of workers.

Migration rates for the elderly (aged 65 and over) are derived from county specific net migration rates computed for the 1970 to 1980 time period for North Dakota. A residual method (see Shryock and Siegel, 1975) was employed in the calculations utilizing data from the 1980 census and vital statistics obtained from the Office of Statistical Services, North Dakota Health Department. It is assumed that this trend best reflects what will occur during the next 20 years.

Institutional Population

Women attending colleges and universities often delay childbearing, therefore the student population in educational institutions with enrollments exceeding 500 are excluded from birth calculations. Enrollment data, both current (1980) and projected, were obtained from the North Dakota Council on Higher Education. It is assumed that enrollments will decline 1 percent annually, based on their projections. The following age scheme is also assumed, due to a lack of age-specific enrollment records.

Class Standing	Age
Freshman	18-19
Sophomore	20
Junior	21
Senior	22
Graduate	23-25

Concurrently, the two major air bases in North Dakota, Minot Air Force Base and Grand Forks Air Force Base, are assumed to maintain constant population levels across all projection years.

Projection Series

Two series of projections are presented in this report reflecting different scenarios. In Series I, it is assumed that lifestyles (e.g., work force participation) and the unemployment thresholds--the approximate level at which out-migration is triggered--remain at current levels (see U.S. Bureau of Census, 1982). Users interested in ascertaining what a continuation of present conditions may mean for the state's population for the next 20 years may find this series useful.

Series II projections portray a shift in various conditions in North Dakota's population. For example, women's labor force participation in the state has increased significantly during the past decade from 35.4 percent in 1970 to 47.9 percent in 1980 (U.S. Bureau of Census, 1982). As a result, the number of in-migrating workers may be altered if this trend continues, since many of the available positions could be filled by women opting to enter the labor market.[2] Also, current administrative policies (e.g., budget reductions in many social services, strategies for a new federalism) may trigger a tightening of the state's economy which may be reflected in a lower unemployment threshold. The user interested in addressing issues which assume such shifts in our economy may find Series II projections more useful.

Table 1 provides a comparison of the two projection series for the state and its eight economic regions. Series II suggests only modest population growth will occur in North Dakota over the next two decades, an annual average of .52 percent. If Series II approximates the state's growth pattern, North Dakota will increase in population by nearly 25,600 residents by 1990 and an additional 46,639 inhabitants by the year 2000. In contrast, Series I projections indicate a slightly higher growth rate, approximately .74 percent annually averaged over 20 years. Accordingly, North Dakota may increase by nearly 58,400 people by 1990 and further expand to more than 757,000 residents by the year 2000.

A more detailed comparison of the state's projected growth pattern is presented in Table 2. In general, the majority of counties are projected to

---

[2] It should be noted that the model does not account for social barriers (e.g., stigmas, socialization) which may hinder women's ability to fill various positions.

continually increase in population during the next 20 years. However, according to the projections, many of the counties may reach their peak population during this decade and begin to decline during the 1990s. Nonetheless, counties with large urban centers (i.e., Burleigh, Cass, Grand Forks, Ward) are expected to sustain continued growth during the next two decades.

Limitations

Population projections are mathematical calculations which indicate the population that would result given a specified base population is subjected to various interacting processes at assumed rates. Although information depicting North Dakota's resident population is relatively accurate, our ability to forecast changes in any socio-economic or demographic process which may alter current population trends is tenuous at best. It is wise, therefore, to utilize these projections with caution; not as the sole element in planning or decision making, but rather as a tool to facilitate such endeavors.

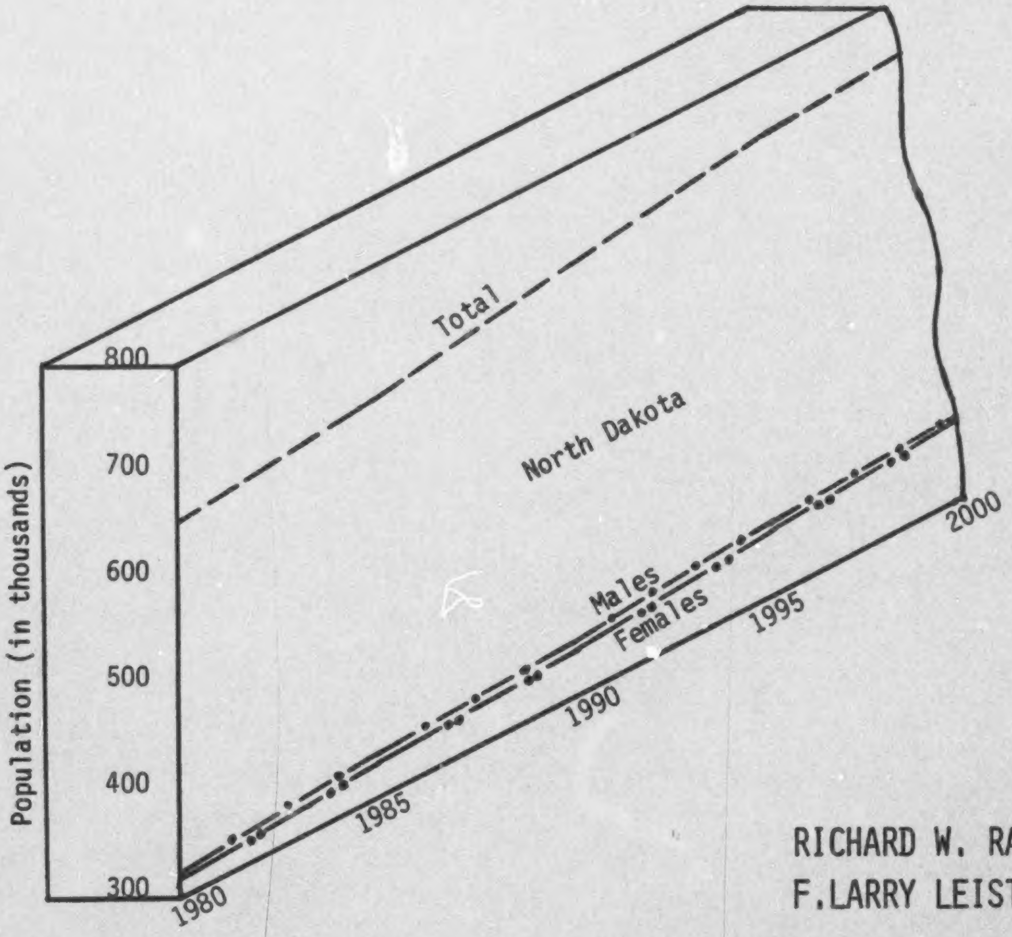
POPULATION PROJECTIONS BY AGE AND GENDER, 1980-2000, FOR NORTH DAKOTA



RICHARD W. RATHGE
F.LARRY LEISTRITZ

Department of Agricultural Economics
North Dakota Agricultural Experiment Station
North Dakota State University
Fargo, North Dakota 58105

Foreword

Population projections are useful tools for planners and policy makers. They provide a basis for assessing the future needs of a specific clientele. Moreover, foresight into increased demand for various public and private services, shifts in land use and health care needs, and numerous other alterations may mitigate detrimental consequences which could otherwise be associated with North Dakota's changing population structure.

Projections, however, are based upon historical trends and thus portray what would occur if population processes were to continue in an assumed manner. This report, utilizing 1980 census data and various current economic statistics within an economic-demographic simulation model, presents projections of North Dakota's population by gender at five year intervals from 1980 to the year 2000.

Acknowledgements

The authors wish to acknowledge members of the advisory committee who served as a review forum for these projections. Their insights, comments, and critical review provided invaluable assistance throughout the project.

Financial assistance for these projections was received, in part, from a grant from the North Dakota State Department of Health for which the authors are grateful. Also, the authors wish to acknowledge the support of the North Dakota Agricultural Experiment Station and the North Dakota State Census Data Center.

Computer programming expertise was provided by William Ransom-Nelson, Rakesh Sharma, and Pai-Sung Yang. Their skills and dedication greatly facilitated completion of these projections, for that we are especially appreciative. Recognition is also given to Rajnish Barua and Babusankar Ranganathan for their assistance in final tabulations and layout.

Population Projections By Age and Gender, 1980-2000, For North Dakota

by

Richard W. Rathge and F. Larry Leistritz*

Introduction

This report presents projections of North Dakota's population by age and gender[1] shown in five year periods from 1980 to the year 2000. Tabulations for the state and its eight planning regions and component counties (see Figure 1) are included. This publication updates previous projections (see Murdock and Ostenson, 1976) by incorporating many of the changes which have recently occurred in North Dakota's population.

Quite dramatic shifts in various aspects of North Dakota's population have occurred during the 1970s. Seventeen of North Dakota's 53 counties expanded their population during the 1970s, nearly three times the number recorded in the 1960s. Moreover, 11 counties exhibited net in-migration from 1970-1980 while an additional 25 counties reported decreases of 10 percent or more in their net out-migration rates for the same period compared to 1960-1970. In contrast, only two counties experienced net in-migration during the decade of the 1960s. Much of the new growth is due to increased energy development, expecially in western counties of North Dakota. Concurrently, the number of births in the state dropped 21 percent compared to the previous decade. Furthermore, the proportion of elderly (65 years of age or older) in North

---

[1] In conducting population analyses, it is important to recognize that policy or planning decisions are often implicitly linked to the expected roles individuals may play. Sensitive to this concern, we utilize the term gender in this report since it encompasses social expectations based on sex, the biological distinction between males and females.

Dakota rose 21 percent above the 1970 level contributing to a marked increase in the median age of North Dakota residents from 26.4 in 1970 to 28.3 in 1980.

In addressing the changes in such dimensions and processes, an economic-demographic simulation model is employed for projecting the state's population. Unlike the cohort-survival method used in earlier tabulations, the simulation model accommodates dynamic populations typical in energy development areas (i.e., western North Dakota). In general, the model enhances our ability to portray what the state's population picture is likely to be in the future by incorporating various modules which provide for input from energy development indicators, nonenergy-related economic and demographic parameters, and residential allocation indices. A discussion of the assumptions upon which these projections are based and guidelines for their utilization follows a brief overview of the economic-demographic simulation model.

Economic-Demographic Simulation Model

Conceptually, the economic-demographic simulation model projects an estimate of employment demand from an economic input-output module and links it with projected labor force availability via a demographic cohort-survival module to determine employment needs (see Leistritz *et al*., 1982 for further documentation). Migration results when the resident population can not fill projected employment needs (in-migration) or in the event of an excess labor force (out-migration). Settlement patterns of new workers and their families are estimated in a separate component of the model.

Employment requirements are derived from estimates of gross business volume--an assessment of economic activity in 13 sectors (e.g., agriculture, manufacturing, construction, trade) of North Dakota's economy from 1960-1980. A correlation of employment in each economic sector, drawn from published sources (e.g., Employment Security Bureau) for the corresponding historical period, with gross business volume provides a trend by which to project employment demand.

Labor force availability is determined from a cohort-survival component which applies a set of age-specific fertility and mortality rates to a given county population for a projected period in order to determine the population at the end of that period. Concurrently, age-gender cohorts (persons of the same gender born during the same period of time) are advanced appropriately through the years--in essence aging the population--while migration rates for the elderly (65 years or older) are applied. Age-gender specific labor force participation rates are then applied to the population to determine labor force availability.

In general, the projection procedure is as follows:

1) The model begins with age-gender specific cohorts at the county level abstracted from the 1980 census of population.

2) Age-gender specific mortality rates are applied to the population, and each cohort is advanced one year.

3) Age-specific fertility rates are applied to women 15-44 years of age to determine the number of children born that year.

4) Migration rates (1970-1980) are applied to those 65 years and older to determine the number of elderly migrating in or out of each county.

5) Employment requirements reflected in gross business volume are calculated for each county.

6) Labor force availability is computed at the county level and matched to the employment needs to determine nonelderly migration (i.e., workers and associated spouses and dependents).

7) The results of the preceeding steps are accumulated to determine the population within each cohort for the first projection year. The process is repeated 20 times, in each instance utilizing the preceeding year's population as a base.

A more detailed description of the projection procedure is available in the simulation model's technical documentation (see Leistritz _et_ _al_., 1982).

Assumptions

Various assumptions are made in the procedures outlined above of which the user of the projections should be cognizant:

Fertility

Age-specific fertility rates used in the model are derived from birth data by age of mother for North Dakota obtained from the Office of Statistical Services, North Dakota Health Department. An average of the total births in each cohort during 1979, 1980, and 1981 is used to control for year-to-year fluctuations in the number of births. Similarly, variations in female cohort sizes are controlled by calculating fertility rates for five-year age groups from 15 to 44 and disaggregating them into single-year age-specific rates. Total fertility, the sum of these age-specific rates for all cohorts, is assumed to be at the current state rate of 2.1 (population replacement level).

It is further assumed that changes in fertility patterns are likely to occur over time. In order to allow for these possible shifts, fertility rates used in the model are adjusted to project national trends, which fluctuate between 1.9 and 2.1 (see U.S. Bureau of Census, 1977), by ratioing North Dakota's 1980 age-specific fertility rates to equivalent national rates. Also, variations in fertility rates among different counties in North Dakota will most likely diminish, so a state rate is employed for all projection years.

Mortality

Statewide cohort-specific survival rates applied to 75 age-gender groups are used by the model to measure mortality. These rates are derived from a 1980 standard life table constructed from population data abstracted from the 1980 census and age-specific mortality data obtained from the Office of Statistical Services, North Dakota Health Department. Year-to-year fluctuations in the number of deaths is controlled by averaging total deaths in each cohort during 1979, 1980, and 1981. Due to the relatively low rates of mortality and limited variation between county rates, 1980 survival rates for the state as a whole are assumed to prevail within each county for all projection periods.

Migration

Migration for those in the working age group (age 14 to 64) is determined in the economic module by comparing employment requirements and available workers, as mentioned previously. Out-migration indicates available workers exceed required demand by a specified parameter; in-migration represents the opposite situation.

Concurrently, migration rates for individuals under age 14 are determined as a function of the level of migrating workers. Based on surveys, worker profiles have been developed assessing various demographic characteristics including those individuals (i.e., children, spouses) who are likely to migrate with the worker. Migration levels of children (those under age 14) therefore are contingent upon the movement of workers.

Migration rates for the elderly (aged 65 and over) are derived from county specific net migration rates computed for the 1970 to 1980 time period for North Dakota. A residual method (see Shryock and Siegel, 1975) was employed in the calculations utilizing data from the 1980 census and vital statistics obtained from the Office of Statistical Services, North Dakota Health Department. It is assumed that this trend best reflects what will occur during the next 20 years.

Institutional Population

Women attending colleges and universities often delay childbearing, therefore the student population in educational institutions with enrollments exceeding 500 are excluded from birth calculations. Enrollment data, both current (1980) and projected, were obtained from the North Dakota Council on Higher Education. It is assumed that enrollments will decline 1 percent annually, based on their projections. The following age scheme is also assumed, due to a lack of age-specific enrollment records.

Class Standing	Age
Freshman	18-19
Sophomore	20
Junior	21
Senior	22
Graduate	23-25

Concurrently, the two major air bases in North Dakota, Minot Air Force Base and Grand Forks Air Force Base, are assumed to maintain constant population levels across all projection years.

Projection Series

Two series of projections are presented in this report reflecting different scenarios. In Series I, it is assumed that lifestyles (e.g., work force participation) and the unemployment thresholds--the approximate level at which out-migration is triggered--remain at current levels (see U.S. Bureau of Census, 1982). Users interested in ascertaining what a continuation of present conditions may mean for the state's population for the next 20 years may find this series useful.

Series II projections portray a shift in various conditions in North Dakota's population. For example, women's labor force participation in the state has increased significantly during the past decade from 35.4 percent in 1970 to 47.9 percent in 1980 (U.S. Bureau of Census, 1982). As a result, the number of in-migrating workers may be altered if this trend continues, since many of the available positions could be filled by women opting to enter the labor market.[2] Also, current administrative policies (e.g., budget reductions in many social services, strategies for a new federalism) may trigger a tightening of the state's economy which may be reflected in a lower unemployment threshold. The user interested in addressing issues which assume such shifts in our economy may find Series II projections more useful.

Table 1 provides a comparison of the two projection series for the state and its eight economic regions. Series II suggests only modest population growth will occur in North Dakota over the next two decades, an annual average of .52 percent. If Series II approximates the state's growth pattern, North Dakota will increase in population by nearly 25,600 residents by 1990 and an additional 46,639 inhabitants by the year 2000. In contrast, Series I projections indicate a slightly higher growth rate, approximately .74 percent annually averaged over 20 years. Accordingly, North Dakota may increase by nearly 58,400 people by 1990 and further expand to more than 757,000 residents by the year 2000.

A more detailed comparison of the state's projected growth pattern is presented in Table 2. In general, the majority of counties are projected to

---

[2] It should be noted that the model does not account for social barriers (e.g., stigmas, socialization) which may hinder women's ability to fill various positions.

continually increase in population during the next 20 years. However, according to the projections, many of the counties may reach their peak population during this decade and begin to decline during the 1990s. Nonetheless, counties with large urban centers (i.e., Burleigh, Cass, Grand Forks, Ward) are expected to sustain continued growth during the next two decades.

Limitations

Population projections are mathematical calculations which indicate the population that would result given a specified base population is subjected to various interacting processes at assumed rates. Although information depicting North Dakota's resident population is relatively accurate, our ability to forecast changes in any socio-economic or demographic process which may alter current population trends is tenuous at best. It is wise, therefore, to utilize these projections with caution; not as the sole element in planning or decision making, but rather as a tool to facilitate such endeavors.
